ABSCHLUSSPROJEKT API

Automatic tests using pytest. Compares results of the modules to reference data.

`test_schroedinger.test_potential (testname)`

Tests whether the potential and eigenvalues match the reference data

Parameters `testname` – Name of the directory the reference data is in.

Reading input and saving output.

`modules.in_out.output (potential, energies, wavefuncs, x_exp, sigma_x, xnew, first, last, path)`

Save potential, eigenvalues, eigenfunctions, expectation value and uncertainty of x into the path folder.

Parameters

- **potential** – Potential of the problem
- **energies** – Energy eigenvalues
- **wavefuncs** – Eigenfunctions
- **x_exp** – The expectation value of x
- **sigma_x** – Uncertainty of x
- **xnew** – x-axis
- **first** – Index of the first eigenvalue/eigenvector to include
- **last** – Index of the last eigenvalue/eigenvector to include
- **path** – Where the output is stored

`modules.in_out.params (file)`

Reads the inputfile.

Parameters `file` – The path to the input file. Usually ‘schroedinger.inp’

Returns A dictionary containing input information.

Creates a plot of the previously calculated results of ‘schroedinger.py’

`modules.plot.visualizer (path, scale)`

script to plot wavefunctions, energies, expectations values and uncertainty

Parameters

- **path** – path to the output of a previous calculation
- **scale** – Scales the wavefunctions

Returns matplotlib subplot containing two plots of given output.

Script to find eigenvalues/eigenvectors of the 1-dim schroedinger equation and calculation expectation values of x for a given problem.

`modules.solver.exp_values (wavefunc, x_min, x_max, n_point)`

Calculating the expectation values and uncertainty of x. Returns $\langle x \rangle$ and σ_x

Parameters

- **wavefunc** – Previously calculated wavefunctions to the problem
- **x_min** – Left end of the x-axis
- **x_max** – Right end of the x-axis
- **n_point** – Number of points the x-axis contains

`modules.solver.solver (potential, mass, x_min, x_max, n_point)`

Script to solve the 1-dimensional, stationary schroedinger equation for a given potential. Returns eigenvalues (energielevels) and normalised wavefunctions.

Parameters

- **potential** – Potential of the problem
- **mass** – Mass of particle
- **x_min** – Left end of the x-axis
- **x_max** – Right end of the x-axis
- **n_point** – Number of points the x-axis contains

Script to find the interpolating function to a given set of support (x,y).

`modules.interpolator.interpolator (x_sup, y_sup, method)`

Used to interpolate the Potential from a given set of points using a given method. The method can either be polynomial, linear or cspline (natural cubic spline)).

Parameters

- **x_sup** – Supporting x coordinates of the potential
- **y_sup** – Supporting y coordinates of the potential
- **method** – Either polynomial, linear or a cubi spline

Returns The interpolation function of the potential.
